Abstract – The redclaw crayfish, *Cherax quadricarinatus*, was introduced to Martinique Island for aquaculture purposes in 2004, in an attempt to revitalize the freshwater crustacean aquaculture sector. In 2015, three wild populations were discovered during an electrofishing survey on fish diversity. In 2018, a specific crayfish survey was performed at night using spotlighting and baited traps at 34 sites throughout the island. The species was mostly found in the center and northern part of the island, specifically, a total of 105 specimens were captured in eight streams and five closed water bodies. We sequenced a 491 base-pair fragment of the COI gene to understand the invasion history and pathway from the presumed source population at the Mangatal hatchery. Among the eight haplotypes found, three were dominant, of which, two occurred in the Mangatal hatchery. As crayfish are sold alive, there is a high risk of further human-mediated introductions across the island hydrographic basins. Thus, the distribution of this species could rapidly expand throughout Martinique freshwater ecosystems, with ecological impacts on native communities yet to be determined and requiring urgent investigation.

Résumé – L'écrevisse à pinces rouges, *Cherax quadricarinatus*, a été introduite en Martinique à des fins aquacoles en 2004, dans le but de revitaliser le secteur de l'aquaculture des crustacés d'eau douce. En 2015, trois populations sauvages ont été découvertes lors d'une étude sur la diversité des poissons par pêche électrique. En 2018, une étude spécifique sur les écrevisses a été réalisée de nuit à l'aide de lampes torche et de pièges appâtés sur 34 sites de l'île. L'espèce a été trouvée principalement dans le centre et le nord de l'île, plus précisément, un total de 105 spécimens a été capturés dans huit cours d'eau et cinq plans d'eau. Nous avons séquencé un fragment de 491 paires de bases du gène COI afin de comprendre l'histoire et le cheminement de l'invasion à partir de la population source présumée de l'écloserie Mangatal. Parmi les huit haplotypes trouvés, trois étaient dominants, dont deux dans l'écloserie de Mangatal. Comme les écrevisses sont vendues vivantes, il existe un risque élevé de nouvelles introductions d'origine humaine dans les bassins hydrographiques de l'île. Ainsi, la distribution de cette espèce pourrait rapidement s'étendre à l'ensemble des écosystèmes d'eau douce de la Martinique, avec des impacts écologiques sur les communautés indigènes qui restent à déterminer et qui nécessitent une investigation urgente.

1 Introduction

The introduction of non-indigenous species outside of their native environmental ranges constitutes a major threat to biological diversity, with significant negative impacts on their native counterparts and their ecosystems (Seebens *et al.*, 2017). Exotic or alien species are found worldwide and among all the branches of the tree of life (Seebens *et al.*, 2017; Blackburn *et al.*, 2019). Among these species, the ones with the highest economic value are widely represented (McQuaid and Arenas, 2009). The redclaw crayfish, also known as the tropical blue crayfish, *Cherax quadricarinatus* (Von Martens, 1868), is a striking example. Native to northern Australia and southern New Guinea (Austin, 1996; Bláha *et al.*, 2016), *C. quadricarinatus* is popular for aquaculture and the aquarium trade because it readily breeds in captivity and grows fast in tropical climates (Jones, 1990; Patoka *et al.*, 2014; Azofeifa-Solano *et al.*, 2017). It has been deliberately translocated for aquaculture purposes or as an ornamental species to a number of countries, many with an equatorial or Mediterranean climate, including: Costa Rica (Azofeifa-Solano *et al.*, 2017), Czech Republic (Patoka *et al.*, 2015), Ecuador (Romero and Jimenez, 2002), Hungary (Weiperth *et al.*, 2018), Indonesia (Patoka *et al.*, 2018), Israel (Karplus *et al.*, 1998; Snovsky and Galil, 2011), Kazakhstan (Uderbayev *et al.*, 2017), Malaysia (Naquiddin *et al.*, 2016), Mexico (Bortolini *et al.*, 2007), Russia (Vodovsky *et al.*, 2017), Singapore (Ahyong and Yeo, 2007), Slovenia (Jaklič and Vrezec, 2011), South Africa (de Moor, 2002; Nunes *et al.*, 2017), Taiwan (Hsieh *et al.*, 2016), Ukraine (Kotovska *et al.*, 2016), the United States of America (Morningstar *et al.*, 2020), Zambia (Lodge *et al.*, 2012) and Zimbabwe (Marufu *et al.*, 2018). Similar to the Louisiana red swamp crayfish, *Procambarus clarkii* (Oficialdegui *et al.*, 2020), live importation of redclaw crayfish has allowed the species to colonize new and often natural aquatic environments either through accidental escapes from hatcheries or ponds, or through direct human-mediated introductions. Because of its broad tolerance regarding water quality, a high reproductive rate and dispersal capacity it has a high invasion potential (Karplus *et al.*, 1998; de Moor, 2002; Tropea *et al.*, 2010), allowing the species to rapidly colonize entire river catchments.

Cherax quadricarinatus was first introduced to Martinique into aquaculture facilities in 2004 from Cuba, according to anecdotal information, in order to reinvigorate the aquaculture industry in the island, which was losing momentum as a result of ecotoxicological problems (in particular *Macrobrachium rosenbergii*). Also, according to anecdotal information, individuals were brought in one time and shared between farmers, but most of them have ceased crayfish farming because pesticide rate in their ponds exceeds limit for the sale of edible products. Because of its highly developed hydrographic networks and its tropical climate, Martinique possesses an optimal environment for this species. Since its introduction, and after escapes or intentional releases, this crayfish is now well established in three streams and one reservoir, according to observations from recent electrofishing campaigns conducted by government agencies, the Direction de l'Environnement de l'Aménagement et du Logement (DEAL Martinique) and the Office de l'Eau (ODE

Martinique), within the framework of the EU Water Framework Directive, aiming at enhancing our knowledge on freshwater biodiversity (2013/2015/2016) (DEAL Martinique and ODE Martinique, 2016). Even if fishing is prohibited by law in Martinican freshwater rivers (R02-2017-12-28-003), it is carried out illegally, but the pressure on *C. quadricarinatus*, although in high demand by local fishermen, is far too low to limit population growth and dispersal. According to fishermen, populations are now found in high densities and the presence of this invasive species may therefore be impacting on the environment and native freshwater communities.

The objectives of this study were: (1) to confirm the taxonomic status of the specimens caught during the surveys by Cytochrome c Oxydase subunit I (COI) barcoding, (2) to update the distribution map of *C. quadricarinatus* in Martinique through trapping and nocturnal surveys in rivers of the island and (3) to understand its invasion pathways through the Martinican territory.

2 Material and methods

2.1 Study area

Martinique is a French volcanic island of 1128 km² belonging to the Lesser Antilles, in the eastern Caribbean Sea (Fig. 1). The region is subject to a tropical climate with two main seasons: the “Carême” and the “Hivernage” and two inter-seasons. The “Carême” corresponds to the dry season, from February to April, with sunny and not very rainy weather with maximum temperatures around 30 °C. The “Hivernage”, lasting from July to November, is the rainy season, with the occurrence of storms or hurricanes. Temperature can reach up to 32 °C and annual precipitation range from 970 mm in the south, more gentle part of the island, to 6000 mm in the mountainous, more tropical northern part of the island (DEAL Martinique *et al.*, 2018).

The Martinican hydrographic network is well developed due to the high rainfall and includes 70 catalogued major streams, fed by numerous small tributaries, both permanent and semi-permanent (Fig. 1) (DEAL Martinique *et al.*, 2018). This provides Martinique with rich terrestrial and inland aquatic ecosystems, with a great diversity of fauna and flora, giving it a high rate of endemism within the West Indies (DEAL Martinique *et al.*, 2018).

2.2 Field surveys

A total of 34 sites were surveyed between the 2nd of March and the 20th of May 2018 (during the Carême and the inter-season), including 20 rivers or streams and five closed water bodies (non-functional hatchery, ornamental ponds or water retention pond) throughout Martinique (Fig. 1). Four sites were sampled in the Lezarde River, the largest river in Martinique. The sampled sites were targeted according to the morphology of the stream (mean depth >20 cm for traps) and on the advice from local fishermen. We also included the four sites where *C. quadricarinatus* had been previously detected: Oman, Manzo, Petit Galion, Lezarde Site 2 (Tab. 1).

Sampling was done using four large baited-traps (80 cm length × 25 cm width × 25 cm height, with mesh of 1 cm × 1 cm

Fig. 1. Cartography of the sampling sites of *Cherax quadricarinatus* together with the presence sites of this species in Martinique Island during 2018 field campaign. Sampling was carried out on permanent streams and in closed water bodies. Cartography was prepared using QGIS 2.18 (Las Palmas) software (QGIS Development Team 2016). The shape of Martinique Island was imported from the database IGN and the streams were found in BD Carthage and BD Topo.

and a single cone-shaped inlet) baited with cassava. Each site was searched by spotlight after nightfall, for 20 min, on a transect of 100 m along the bank. After that, the traps were placed on stream beds or water holes (around 10 m from each other) and collected the next morning. Two trapping sessions were conducted at each site on two successive days. The site was considered as positive if at least one crayfish was caught during one of the two capture sessions or if crayfish were observed using spotlighting surveys at night.

Upon capture, individual crayfish were sexed, and total length was measured from the rostrum to the telson (to the closest 0.1 cm). One walking leg was collected from each captured individual and subsequently stored in 90% ethanol, in order to perform further analysis (DNA extraction, PCR and COI sequencing) to confirm the taxonomic status of crayfish in Martinique. The collected individuals were euthanised and not returned to the streams according to French law on invasive species (law n° 2016–1087 of August 8, 2016).

2.3 Samples collection and DNA extraction

A total of 105 individuals were analysed: 84 caught in the wild and 21 individuals were bought at the Mangatal Hatchery (Tab. 2). DNA extraction was performed from a fragment of

leg muscle tissue using the Qiagen DNeasy® Blood & Tissue Kit protocol. The tissue was first dried, put in 180 µL ATL buffer and crushed with a sterile pestle. Twenty µL proteinase K was added to each tube and samples were then vortexed for 15 s before incubation at 56 °C until total lysis of tissue. Each sample was filled with 200 µL AL buffer and 200 µL of 100% EtOH. Samples were vortexed thoroughly, pipetted into a DNeasy Mini spin column and centrifuged at 6000 g for 1 min. Two washing steps were done on the column with AW1 and AW2 buffers. Finally, DNA was eluted by adding 200 µL Buffer AE and stored at –20 °C until further analysis. The DNA concentration was measured by Nanodrop® ND 100 spectrometer (Nanodrop Technologies, Wilmington, USA).

2.4 COI mtDNA analysis

A fragment of COI gene was amplified by PCR using the “universal” primers for invertebrates (LCO1490 and HCO2198) previously designed by Folmer *et al.* (1994). For each individual, PCR was performed following the protocol in Chucholl *et al.* (2015): 2.5 min at 95 °C for the initial denaturing step, followed by 35 cycles of 45 s at 95 °C; 1 min at 48 °C and 1 min at 72 °C. The final elongation step was 10 min at 72 °C. Amplified products were purified and 1/10 diluted

Table 1. Summary of the 34 sites surveyed during the study, including 20 rivers (29 sites) and 5 closed water bodies (non-functional hatchery, ornamental ponds or water retention pond).

Site	GPS coordinates	Detection year	Type of habitat	First capture effort	Second capture effort	Sex-ratio (F:M)	Size range (cm)

GPS coordinates and detection year were added. For each site, the number of *Cherax quadricarinatus* caught was noted after the first and second capture effort. Individuals were sexed and measured. (–) indicates no value because of no capture of red claw crayfish.

* A visual observation of crayfish with no capture.

before sequencing on an ABI PRISM 3130xl automated sequencer (PE Applied BioSystems, Foster City, USA). Both forward and reverse primers were used for sequencing, and the resulting sequenced fragments were aligned and edited using Sequencher® (version 5.4, 2016) formatted with the reference insertion of Mendeley. The taxonomic assignment was assessed with BLASTn 2.10.1 (Madden, 2002) comparing COI sequences to the non-redundant database of NCBI (Version August 2020). A multiple alignment was performed with ClustalW implemented in BioEdit version 7.2.5 (Hall, 1999). This was then trimmed with GBLOCKS version 0.91b (Talavera and Castresana, 2007) to remove ambiguously aligned regions, and to maximize the resulting alignment length, we used the less stringent options to obtain a 491 nucleotides alignment length. All the newly generated sequences were deposited on NCBI GenBank under the accession numbers MW300737 to MW300837. We also

added available sequences from GenBank comprising one sequence from Australia (DQ006294.1), one from Malaysia (NC_022937.1) and four from Indonesia (KX377345.1 to KX377348.1). A haplotype network was constructed based on the polymorphic sites of the trimmed COI sequences using the Median-Joining method implemented in PopART software version 1.7 (Leigh and Bryant, 2015) and genetic distance among haplotype and nucleotide diversity were also calculated with the same software.

3 Results

3.1 Taxonomic status

All crayfish sampled in Martinique belonged to the species *C. quadricarinatus* with a percentage of identity of COI

Fig. 2. A haplotype network using COI sequences (491 nucleotides length) of *Cherax quadricarinatus* collected in Martinique. A haplotype network inferred by a Median-Joining method, using 111 COI sequences of *C. quadricarinatus* populations from 10 different locations in Martinique (105 individuals), from Indonesia (four individuals), from Australia (one individual) and from Malaysia (one individual). The size of each circle represents the frequencies of the haplotype, with each colour showing the geographical origin of the isolates. Hatch marks indicate the numbers of mutations between haplotypes.

sequences of 98.98 ± 0.34 with *C. quadricarinatus* sampled in Malaysia (Accession number: KF649850.1) (Tan *et al.*, 2015), $99.19\% \pm 0.34$ with those from Indonesia (Accession number: KX377345.1) (Patoka *et al.*, 2016) and $99.63\% \pm 0.35$ with those from Australia (Accession number: DQ006294.1) (Shull *et al.*, 2005).

3.2 Distribution of *cherax quadricarinatus*

Among the 34 sites surveyed, crayfish were detected at 16 sites including eight streams and five closed water bodies, with *C. quadricarinatus* being recorded at ten new sites (six streams: Lorrain, Coulisttes, Petite Riviere Site 1, Grand Galion, Petite Lezarde and Cacaos, and four closed water bodies: Chateau Gaillard, Jardin Emeraude, Habitation Ceron and Morne Rouge) (Tab. 1). All sites in the Lezarde river harboured crayfish over a distance of 15 km from upstream to downstream. In total, in the wild, 111 individuals were captured (56 females and 55 males) with highest numbers at Site 1 of the Lezarde river (29) (the most downstream) (Tab. 1; Fig. 1). Total lengths of crayfish ranged from 4.9 cm (Manzo and Grand Galion) to 22.1 cm (Lezarde Site 1) (Tab. 1). No crayfish were caught or observed in the Oman river where specimens had been previously detected in 2014 (Tab. 1), or in the Carbet flowing only 10 meters from the hatchery's ponds (Fig. 1).

3.3 Geographic distribution of the haplotypes

A total of eight haplotypes were found in Martinique (H1–H8). The first (H1) included the majority of individuals (45), consisting of individuals from Lezarde river (24), Grand Galion (9), Mangatal hatchery (5), Petite Riviere Site 1 (5), Manzo (1) and Morne Rouge (1) and was identical to one of the haplotypes from Indonesia. The second major haplotype (H2) included 39 individuals from the Mangatal hatchery (12), Petite Lezarde (10), Lezarde river (5), Coulisttes (4), Morne Rouge (3), Manzo (2), Cacaos (1), Petite Riviere Site 1 (1) and Lorrain (1). The H3 haplotype was represented by individuals from Manzo (6), Cacaos (4) and Coulisttes (1) and was identical to reference haplotypes from Indonesia and Australia. The H4 haplotype contained individuals from Mangatal hatchery (4) and from Manzo (1). The H5 haplotype was only found in two individuals from Grand Galion. The H6, H7 and H8 haplotypes were rare, being represented by one individual each from Petite Riviere Site 1, Cacaos and Petite Riviere Site 1, respectively. Only three haplotypes (H1, H2 and H4) were found among the 21 crayfish sampled from the Mangatal hatchery. Haplotypes H9 and H10 contained one individual each, from the reference haplotypes from Indonesia and Malaysia (Figs. 2 and 3; Tab. 2). The mean nucleotide diversity among all haplotypes was 0.0014.

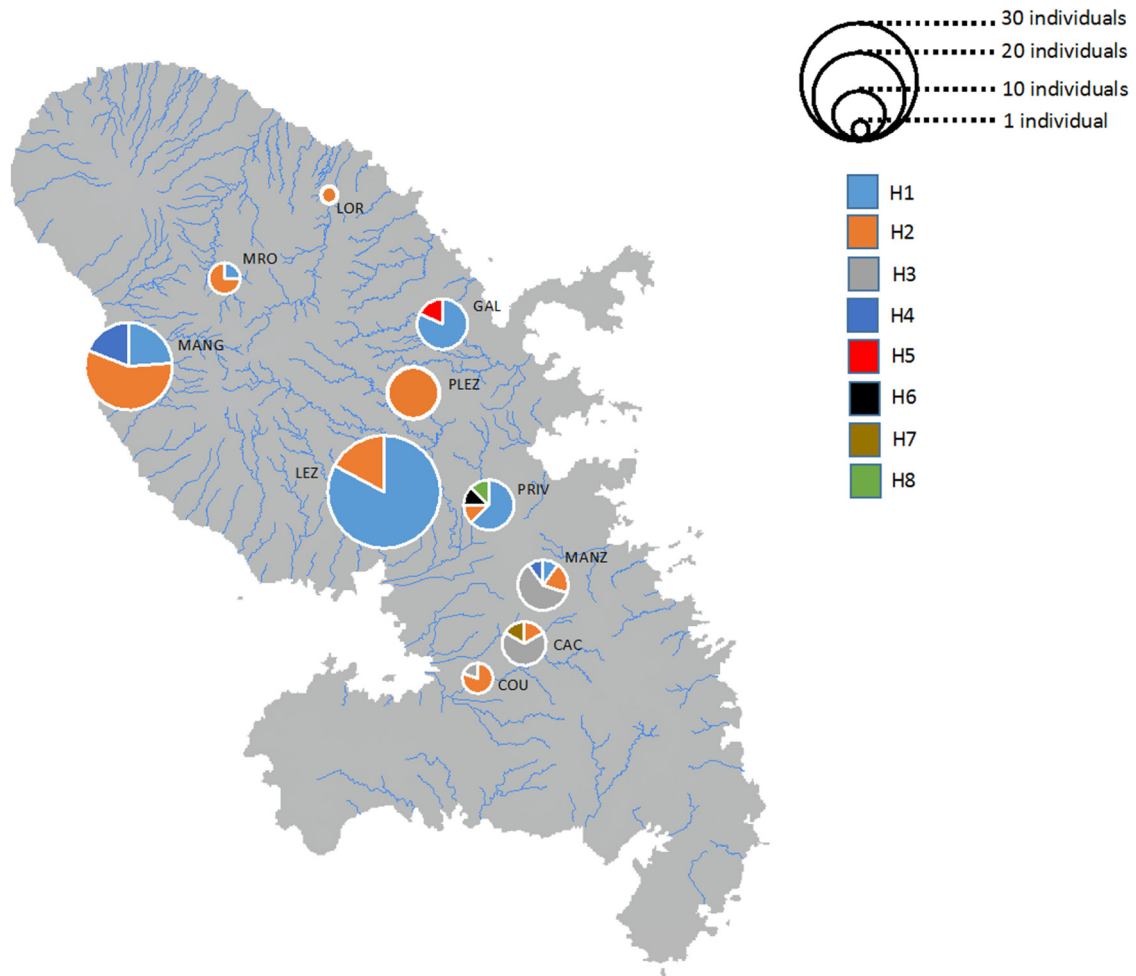

Fig. 3. Haplotype frequencies of *Cherax quadricarinatus* from 105 individuals sequenced in the 10 different locations in Martinique. Using data from Table 2 and Figure 2, diagrams are built, proportionally to the number of sequenced individuals, and each haplotype (H1–H8) was differentiated by one colour. Site names are encoded as follow: Lorrain (LOR), Morne Rouge (MRO), Mangatal (MANG), GAL (Grand Galion), Lezarde (LEZ), Petite Lezarde (PLEZ), Petite Riviere (PRIV), Manzo (MANZ), Cacaos (CAC) and Coulisses (COU).

Table 2. Inventory of the 111 red claw crayfish COI sequences used to carry out the haplotype network analysis.

Populations	Haplotypes (Number of individuals)										Total number of individuals
	H1	H2	H3	H4	H5	H6	H7	H8	H9	H10	
Mangatal	5	12	0	4	0	0	0	0	0	0	21
Grand Galion	9	0	0	0	2	0	0	0	0	0	11
Lezarde	24	5	0	0	0	0	0	0	0	0	29
Coulisses	0	4	1	0	0	0	0	0	0	0	5
Petite Riviere Site 1	5	1	0	0	0	1	0	1	0	0	8
Petite Lezarde	0	10	0	0	0	0	0	0	0	0	10
Cacaos	0	1	4	0	0	0	1	0	0	0	6
Lorrain	0	1	0	0	0	0	0	0	0	0	1
Manzo	1	2	6	1	0	0	0	0	0	0	10
Morne Rouge	1	3	0	0	0	0	0	0	0	0	4
Indonesia	1	2	0	0	0	0	0	0	1	0	4
Australia	0	0	1	0	0	0	0	0	0	0	1
Malaysia	0	0	0	0	0	0	0	0	0	1	1
	46	41	12	5	2	1	1	1	1	1	

105 of them are from individuals collected in Martinique, with various number of sequences per population, four from Indonesia, one from Australia, one from Malaysia.

4 Discussion

Our results showed that the redclaw crayfish is now well established in the Martinican hydrographical networks, with 16 populations identified since its first introduction in 2004. The situation is alarming because 10 new populations were discovered since the previous survey in 2015. This number is probably an underestimation of the real situation for several reasons: (i) not all streams have yet been surveyed, (ii) capture efficiency of crayfish by traps depends on population size (Harper *et al.*, 2018) and activity of crayfish, which can be dependent on meteorological and hydrological conditions and lunar cycles at the time of trapping (Grandjean *et al.*, 2000).

Our results also showed that this crayfish, once introduced, can quickly colonize an entire watershed, as revealed in the Lezarde watercourse where the crayfish were sampled at four sites along 15 km of the river. This result confirms the high dispersal capabilities of this species as also reported by Nunes *et al.* (2017) with an average dispersal rate of 6.6 km/year. Surprisingly, the redclaw crayfish was not caught in three sites of the Carbet River adjacent to the Mangatal hatchery's ponds. This can be explained by the fact that this river has a torrential flow which would not favour the persistence of *C. quadricarinatus* which are found mainly in lentic or more stable and slowly flowing lotic systems (Jones, 1990).

The number of individuals caught varied among sites and ranged from 0 to 29 suggesting some populations may be present at high density, for example in the Lezarde. This is not really surprising, because *C. quadricarinatus* is found in Martinique freshwater ecosystems favourable for its development, suggesting a general absence of both competing species and large predators (Lim *et al.*, 2002). The physical parameters measured in this study revealed a temperature range from 25.4 to 28.8 °C with oxygen concentrations from 2.77 to 8.06 mg/L and pH from 6.78 to 7.49 in the sites where crayfish were present (Supp. Data 1). These ranges are in accordance with the ecological preferences of *C. quadricarinatus* (Karplus *et al.*, 1998; de Moor, 2002; Tropea *et al.*, 2010). In these conditions, females could reach sexual maturity within four months and generate up to five broods per year (de Moor, 2002; Bortolini *et al.*, 2007; Tropea *et al.*, 2010; Arzola-Gonzalez *et al.*, 2012; Mangatal, local farmer, *pers. com.*) which could explain their rapid expansion and their high density in the Lezarde river. These ecological conditions found in the rivers of Martinique seem to be excellent for the growth of this crayfish confirming by the size of trapped crayfish, up to 22 cm in total length (and 214 g) for the largest one in Lezarde river. These appear to be larger than those caught in Costa Rica, with a maximum total length of 9.22 cm (Azofeifa-Solano *et al.*, 2017). As a result, this crayfish represents one of the biggest species present in these fresh waters, able to capture and consume large prey species and having significant ecological impacts due to their broad dietary preferences and population densities.

The introduction of *C. quadricarinatus* to Martinique remains poorly documented. According to the popular opinion, however, the red claw crayfish was introduced in 2004 from Cuba when a few specimens (around 20) were brought by the owner of the major crustacean hatchery on the island (Mangatal *pers. com.*). Results from COI sequencing from

21 individuals sampled from the Mangatal hatchery revealed three haplotypes (H1, H2 and H4) of which H1 and H2 haplotypes were represented in most of the sites where crayfish were trapped. This is therefore consistent with the Mangatal stock being the principal origin of most of the populations established in the wild in Martinique and it is not surprising because the crayfish are sold alive as a food item. They are valued as food by local people and sold at a high price (24 euros/kilo), this increases the likelihood of their introduction and eventual establishment into local ponds and watercourses enhancing the availability of this species. Two additional haplotypes were recorded in three geographically closed populations (Manzo, Coulisses, Cacaos), with at least three mutations, that were not present in the Mangatal pool. As the initial stock came from 20 individuals including both males and females, it would seem unlikely the 8 haplotypes came from this original stock. So, we cannot exclude other independent introductions of this crayfish from older farming activities. Redclaw crayfish was previously sold (before the prohibition by the law on Exotic Species (JORF n°0229 of 19th september 2020 Text n° 3)) in pet shops in Martinique until 2019. Being highly regarded by aquarists, as it often exhibits a strong blue color in aquaria, it could have been bought from local pet shops or imported and released in the wild on a number of occasions. High level of genetic variability has been also recorded for other translocated species in Europe such as *Procambarus clarkii* (Oficialdeguí *et al.*, 2019) and *Pacifastacus leniusculus* (Petrušek *et al.*, 2017), potentially also reflecting multiple introductions.

Although no documented impacts have been reported on the ecosystem in Martinique, invasive crayfish are known to have profound impacts on freshwater communities (plants and animals) due to their opportunistic, omnivorous and predatory nature. This can affect the trophic chain at all levels, by competing with autochthonous species or preying on them and perturbing the entire ecosystem functioning (Loureiro *et al.*, 2015; Jackson *et al.*, 2017; Lang *et al.*, 2020). For example, several studies have shown that *P. clarkii* (Jackson *et al.*, 2014; Loureiro *et al.*, 2015; Lang *et al.*, 2020), *P. leniusculus* (Jackson *et al.*, 2014; Vaeßen and Hollert, 2015) and *Faxonius virilis* (formerly *Orconectes virilis*) (Jackson *et al.*, 2014) can cause strong decreases in species richness of insect larvae and mollusks through predation after their introductions to a new location. Studies also suggest a decrease in the abundance and diversity of aquatic plants and animals is directly related to crayfish density (Gherardi and Acquistapace, 2007; Rodríguez-Pérez *et al.*, 2015). Thus the presence of *C. quadricarinatus* could be having a significant impact on Martinique freshwater biodiversity especially where this crayfish reaches high levels of abundance such as in the Lezarde river. The rapid establishment and dispersal of this crayfish may have been facilitated by the limited number of natural crayfish predators in freshwater ecosystems in Martinique. So far, the only known effective native predators found in Martinique freshwaters seem to be eels, commonly used in biological control of crayfish in Europe (Aquiloni *et al.*, 2010). Only *Anguilla rostrata* occurs in Martinique (Lim *et al.*, 2002), but this species is now placed on the red list of species and by the IUCN as an endangered species. Because of their declining population, eels are unlikely to be able to reduce the crayfish densities and dispersal in Martinique.

Using traditional sampling methods, the current situation shows a spread of *C. quadricarinatus* throughout the Martinican water systems. The use of the environmental DNA (eDNA) technique in further studies could provide a more accurate measure of the distribution of *C. quadricarinatus* in Martinique streams. Recently, eDNA has been used to detect crayfish species, both endangered and invasive (Dougherty *et al.*, 2016; Agersnap *et al.*, 2017). This technique is becoming a very effective tool in the early detection of invasive species or in monitoring communities with greater efficiency than direct methods such as trapping or visual observation (Biggs *et al.*, 2015; Hänfling *et al.*, 2016).

In the global context of preservation of biodiversity, it seems urgent to develop strategies to prevent establishment of further new populations and investigating the impact of redclaw crayfish on the natural environment and native freshwater communities.

Acknowledgements. We thank the Direction de l'Environnement, de l'Aménagement et du Logement de Martinique and the Office de l'Eau de Martinique for their financial support and the Centre National de la Recherche Scientifique and the University of Poitiers for the provision of all the equipment necessary to carry out the study.

Supplementary Material

Supplementary data 1: Environmental parameters (Temperature, oxygen concentration and pH) measured at each site prospected during baited-trap survey, with Ponsel Mesure Odeon field tool.
